effect of anesthesia may result in those who have had larger doses of anesthesia having a better outcome than those who had light anesthesia, while in neonates who have only minimally invasive surgery any neurotoxic effect and hence poor neurobehavioral outcome may be greater in those who had the greater exposure to anesthesia compared with those who had a light anesthetic.

This book, written by leading Japanese experts in the field, describes the latest findings on the neurotoxicity of anesthetics for the developing brain, postoperative delirium and cognitive dysfunction. It describes the risk factors for postoperative cognitive dysfunction in elderly surgical patients.

General anesthesia and sedation can be achieved by inhaled or intravenous administration of specific drugs. Both GABA agonists and NMDA antagonists have been implicated in causing anesthetic-induced developmental neurotoxicity (AIDN). Both the short-term and the long-term neurocognitive effects of general anesthesia should be considered.

These findings suggest that CypD may contribute to the developmental anesthesia neurotoxicity and would facilitate the mechanistic investigation of neurotoxicity in the developing brain (Figure 7).
